

## **WCC Modelling Protocol**

# Advice Note 03.1 - Model Analysis and Reporting

## **Purpose of This Note**

- 1. This note sets out expectations around the reporting of outputs from the suite of Microsimulation models owned and licenced by WCC.
- 2. It is intended to provide guidance on the core elements which WCC consider reasonable to request and would request reported in model outputs when undertaking an assessment.
- 3. It should be noted that the outputs that are identified within this Note are considered to be the standard outputs that users of the model should expect to have to provide to the County as the evidence base for a Transport Assessment.
- 4. It does not preclude the right of WCC to request additional model outputs when bespoke analysis is considered appropriate in relation to a specific impact and or issue that has been identified within the study area or modelling.
- 5. Types of bespoke analysis which may be requested have been documented later within this Note.

## Responsibilities

- 6. When undertaking an assessment of the outputs derived using WCC microsimulation models it is the responsibility of the licensee and/or their consultant to review the outputs and identify any problems as well as any potential solutions thereto.
- 7. If the modeller responsible for the technical work is a modelling consultant on the existing WCC modelling framework then they are only responsible for the technical work.
- 8. The modelling consultant should not provide interpretation of the results since this would represent a conflict of interests when considering the need to maintain the technical independence of the modelling work. Thus, any interpretation and/or scheme proposals arising from the modelling work should be provided by the licensee and their transport consultant rather than the modeller(s).
- 9. WCC is responsible for accepting and reviewing the modelling submission provided it has been issued to WCC in accordance with the requirements set out within Advice Note 07 (Guidance on Model Submission).

#### <u>Requirements</u>

10. WCCs LTP4 and the NPPF both set out expectations relating to the need for Transport Assessments to be completed to support development proposals.

- 11. As part of that assessment process, it is expected that the impact of traffic generated by the development proposals will be assessed and, where appropriate, measures will be considered to reduce any impacts down to a level which may be considered acceptable.
- 12. WCCs traffic models are expected to be used to identify the extent of any impacts which may occur through the delivery of development proposals.
- 13. Having identified the level of impact, where it is considered necessary that interventions will be required to reduce the impacts, they should also be tested within the same modelling suite, and the evidence provided within the accompanying transport assessment.
- 14. WCC requires the reporting to be undertaken in line with the approach set out within this advice note so that WCC can be confident that a thorough assessment has been completed, and more importantly, any impacts identified through the assessment are within acceptable tolerances or will be mitigated appropriately.
- 15. WCC recognises that developers may wish to adopt their own approach to reporting and presentation of outputs. Where this is the case (i.e. developers and their consultants wish to present their own outputs) we request that developers to also submit the information set out within this Advice note to ensure the assessment can be considered sufficiently robust and, furthermore, to ensure that any impacts can be judged on a comparable basis to other applications and developments being considered across the county. This is particularly helpful in the context of reporting back to non-technical stakeholders who are already familiar with the process set out within this note.
- 16. Finally, in the matter of severity, WCC considers that it is not WCCs responsibility to undertake the necessary analysis to determine if a residual impact is likely to be severe in the context of NPPF. There is an expectation that, through the traffic modelling, developers will be able to demonstrate whether a residual impact is likely to be severe both in the context of impact on operation levels for existing and future users of the network and network safety. This requires developers and their consultants to provide the information and interpretation to WCC to support the case for development rather than assuming WCC will form a judgement on the basis of the information extracted from the model without interpretation.

## **Core Reporting**

- 17. WCC consider that any reporting of model outputs should be undertaken on a staged basis as follows:
  - Key network performance indicators should be extracted for the purposes of comparing the strategic implications of every option being considered. They are a high-level measure of general trends and patterns within model scenarios. They consider changes across the entire study area (journey times, delays, completed trips) and are therefore not, in isolation, a reliable indicator of impact.
  - Localised impact analysis in the form of changes in:

- Link attributes (flow & speed)
- Queuing at junction approaches
- Journey times along key routes
- Bespoke analysis may then be requested to enable detailed statistical analysis of the
  outputs extracted from the modelling to be completed. The purpose of this analysis
  will be to establish, in areas where impacts are less clear, the statistical significance
  of the impacts observed and, furthermore, the pattern of impact which will enable
  a better understanding of the need for further investigation and/or additional
  mitigation to be established.
- 18. It is recognised that the scale of development will directly impact upon the scope and level of detail required when reporting the model outputs and therefore *it is expected that the outputs that will be reported upon and the extent of the area covered by the analysis will be agreed with Warwickshire County Council in advance*.
- 19. It is also recognised that the extent to which an impact may (or may not) be considered significant also relies on aspects which are outside of the modelling analysis. The existing situation at a location (safety concerns, volume of vulnerable users, air quality concerns) must be considered alongside the extent of impacts identified through the analysis and where an impact is identified but mitigation not proposed, justification for how the existing situation will not be adversely impacted upon to an unacceptable level should be provided.
- 20. The following provides an overview of the different measures which are expected.

## **Key Network Performance Indicators**

- 21. The first assessment measures that are expected are those which report on the overall model performance, the purpose of these measures is to provide high level comparisons between scenarios and, furthermore, to provide an initial indication of network performance to enable the early identification of any issues.
- 22. The measures which are expected are outlined as follows:

## **Model Stability**

- 23. The deterministic nature of microsimulation models means that WCC recommends model stability is assessed first to ensure that the models are sufficiently stable that they can be relied upon for the more detailed stages of analysis.
- 24. Model stability can most simply be assessed by revieing the congestion profiles and traffic volumes assigned and contained within the traffic models. Where figures such as 'peak vehicle' numbers or 'number of vehicles on the network at simulation end' suffer very high levels of divergence then this may indicate that a model is unstable.
- 25. Where model stability has been particularly poor, the extent of instability and the potential reasons which are contributing to instability must be assessed to allow the reliability of the model network across the various scenarios to be better understood.

- 26. Model stability statistics should be quoted within the initial phase of modelling analysis but it is not expected that they would be presented in any final analysis if the models are considered to be sufficiently stable. If model stability is not quoted as a model output, then it is assumed that the model will be sufficiently stable, but the onus is on the modeller to confirm this.
- 27. It is critical that the analyst demonstrates that a sufficient number of runs has been undertaken to inform the analysis and, furthermore, it should be noted that WCC do not consider less than ten random seed runs per time period to be acceptable in any circumstance.

## **Network Wide Statistics**

- 28. Statistics used in the analysis of network wide statistics have been obtained from assessing each individual trip that has occurred within the network. This information is collected within Paramics via the 'Trips-all' file and contains information specific to each individual trip completed within the model period. This information is aggregated and processed to provide the following comparative statistics:
  - Average Time (seconds) The average travel time of a completed trip during the model simulation period.
  - Average Speed (Km/h) The average speed travelled by all vehicles that completed a journey during the model simulation period.
  - **Completed Trips (vehicles)** The number of completed trips recorded during the model simulation.
- 29. The first two measurements are averages so can be used to compare between the various scenarios. The final measurement is an absolute and is dependent on congestion on the network (as this will prevent trips from completing) and the demand within the model (i.e. the number of trips actually trying to complete). As demand differs between scenarios, as well as small variations between runs of the same scenario, we cannot expect the number of completed trips to be the same. However, as the demands do not differ significantly it can still provide an indication of the relative congestion on each network.
- 30. All of these measures should be extracted using the Trips-All file within Paramics as this ensures that all completed trips are considered within the analysis.
- 31. The results should be presented for the modelled periods as a minimum. Supplementary analysis of the peak hours may also be requested.
- 32. The measures are derived for the whole model network and so consider all trips which are assigned to the model and the entire model network. In some instances, there are 100,000+ trips assigned across the modelled period and over 200km of road network included in the model.
- 33. It is not expected that localised development proposals would induce significant differences in these measures, if they do then it is likely a very significant issue may be present on the network. However, localised impacts will be almost indiscernible at this level of reporting and

- so WCC does not consider it appropriate to rely on the level of change identified within the network wide statistics as a means of demonstrating an impact is insignificant.
- 34. Ten seconds in the context of a local journey may not be considered significant but 10s added to over 100,000 trips within a single time period is likely to be significant. Either way, only after analysis of the network operation is completed, in line with the approach set out below, can it be determined if an impact is likely to be acceptable or not.

## **High Level Analysis**

- 35. Having completed the analysis of the key network performance indicators, it is essential that additional analysis of the impacts on key routes and junctions within the modelled area is completed. This will enable WCC to discern the extent of any impacts identified on the transport network through the traffic modelling.
- 36. For each of the wide area models that WCC hold, a map can be made available which illustrates the standard set of junctions and routes which are readily configured within the modelling.
- 37. Whilst WCC may provide a map of the key areas identified within the modelling, it is considered appropriate that this is agreed as sufficient between all parties prior to any modelling being completed. As has already been highlighted, the scope of any assessment will be dependent upon the size of development being considered as well as the location.
- 38. It is possible that the extent of reporting may be reduced for smaller developments or, for larger developments (or developments located in areas not already subject to detailed reporting) additional junctions and routes may need to be added into the analysis. The extent of reporting required should be discussed and agreed with WCC in advance of commencement of any modelling.
- 39. The initial, high-level analysis, is expected to focus on the differences based on hourly values whereas detailed analysis should break impacts down into the more detailed 5 and 10 minute intervals. The detailed, analysis is discussed within the next chapter of this note.
- 40. For the high level, hourly analysis, the following parameters should be adopted:
  - **Hourly Queuing** analysis should be based on the average hourly maximum queue length and should be presented in vehicles.
  - Hourly Journey Times differences should be presented as the average journey times, in seconds, for all vehicles which traverse the journey time route within the modelled hour.
  - **Link Flows** differences in vehicles are requested to enable an assessment of the significance of changes in the area and potential implications for link capacity.
  - **Link Speeds** alongside the flow changes, differences in speeds on links should also be provided.
- 41. Further details on the expected reporting requirements, concerning each of the parameters listed previously, is documented within the following section:

#### **Hourly Queueing**

- 42. It is expected that, at the highest level, queues should be presented based on average hourly maximum queue lengths. WCC preference is that these are reported in vehicles.
- 43. It is recognised that the hourly maximum represents the the worst case average across model runs, but it is considered that this is an appropriate parameter to adopt for the initial analysis. Detailed analysis and sifted, detailed later within this note, provides additional opportunities to investigate the appropriateness of this robust parameter, particularly when adopted in isolation.

#### **Hourly Journey Times**

- 44. Journey time information can be reported in seconds or MM:SS format. In line with TAG guidance, routes should be broken down into key sections to enable the analysis to identify the junctions and pinch points on along the route which experience the greatest impacts.
- 45. Delay on routes made up of multiple paths, should be presented for both sections and full route with the full route being presented as the aggregate of the sections and not via a separate path for the entire length of the journey time route (as this is likely to result in a lower sample size since Paramics only reports the journey times of vehicles which complete the entire path).

#### **Link Flows**

- 46. Link flows should be expressed in total vehicles on an hourly basis. WCC may also wish to see the HGV totals on key links if these movements are a concern. This would be agreed separately if HGV flows are required, they are not expected as standard.
- 47. WCC may also request that the significance of any changes in flows be determined, in part, through the application of GEH criteria although it is recognised that this parameter is primarily intended for assessing model development standards it is considered a useful measure, further analysis as to how detailed link flow analysis may be undertaken is provided later within this note.

#### **Link Speeds**

- 48. Although speed is impacted upon by a number of different aspects, including capacity and any congestion at adjacent junctions, link speed is still considered a useful indicator of the performance of the network in key areas and should be provided as standard.
- 49. There are no tests to determine whether an impact on a link speed is considered significant, but the link speeds should still be reported alongside the link flows as comparatively the two measures enable more detailed analysis to be undertaken. For example, large increases in flows may not necessarily be considered to impact upon the network if it is within the theoretical capacity of the link and the flows are achieved without a substantial drop in the speeds in the same area.

## Reporting

- 50. Reporting should encompass all areas identified within the reporting requirements that accompany the wide area models. If an analyst considers that an alternative, smaller, area should be assessed then this should be discussed in advance with WCC and agreed before any results are presented.
- 51. WCC consider that one of the key benefits of the suite of wide area models which they hold is that it enables impacts across a wider area to be considered and, in particular, the interaction of junctions therein.
- 52. On that basis, analysts should expect to report outputs for all the key areas identified and not just the immediate area around the development proposals.
- Reporting of the high-level analysis should be seen as <u>a precursor to the provision of more</u> <u>detailed analysis</u> at appropriate locations where it is identified that the development will influence conditions on the network. Guidance on how 'influence' may be defined is set out later within this Note.
- 54. Reporting should consider **both** the periodic and peak hour (i.e. the core 08:00 to 09:00 and 17:00 to 18:00 hours) impacts unless WCC advise otherwise. Key network performance indicators and some of the GIS reporting may focus on the periodic impacts whilst the location specific and more detailed analysis reported subsequently may be provided on an hourly or even smaller (e.g. 5 minute) interval basis.
- 55. WCC may also wish to see analysis provided for areas within the model where impacts do not manifest but that there is an expectation of impact due to localised constraints or other conditions not yet accounted for within the model (due to age of data, new issues as a result of growth, areas of the model where data did not originally exist for calibration, etc).
- 56. Reporting should be accompanied by visual aids wherever possible as this will enable both officers and members to understand the development implications in a much more engaging manner than is achieved through the provision of data tables in isolation.
- 57. WCC have promoted the use of GIS to present the outcome of key model scenarios, and this is available for review in the various Strategic Transport Assessments that have been produced to support the Boroughs and Districts of Warwickshire through the Local Plan determination process.
- 58. In doing so, WCC have defined a set of parameters for the STA work which are considered appropriate in the context of the Local Plans and the relative uncertainties associated with both the delivery of the growth levels assumed and the overall infrastructure requirements.
- 59. When utilising the models to inform the analysis of impacts to support Transport Assessments and other, development specific planning requirements, it is considered essential that the grading of impacts be tightened and that smaller impacts may be classified as significant at this stage, to aid the identification of areas for additional, more detailed, analysis to be completed.

- 60. In all cases the baseline assumptions for any GIS analysis should be a scenario in which the development proposals and/or schemes are not considered. This would either be in the form of a Base model or a Reference Case model.
- 61. When selecting the Reference Case to inform the comparisons it is also important that the year selected does not occur at a point after it is considered likely that the development will come forward (for example a 2027 Development scenario must not be compared to a reference scenario representative of a year which falls after 2027).
- 62. WCC do not have any strict rules concerning the grading of differences when presenting queueing and delay analysis through GIS but offer the following suggestions for the analysis of both measures:

#### **Queueing Criteria:**

- 63. The following queue comparison criteria is suggested for consideration when assessing queues:
  - Moderate Increase (an increase in queue lengths of between 5 and 10 vehicles)
  - Significant Increase (an increase in queue lengths of between 10 and 20 vehicles)
  - Very Significant Increase (an increase in queue length of over 20 vehicles)

#### **Journey Time Criteria**

- 64. The following journey time comparison criteria is suggested for consideration when assessing journey time impacts along key routes. The following criteria also assumed that the starting journey time for the comparative route exceeds 60 seconds:
  - No Significant Change A difference in journey times of up to +5% falls within this
    category.
  - Moderate Increase An increase in journey times of more than 5% but less than
     10%.
  - Significant Increase An increase in journey times of more than 10% but less than
     20%.
  - Very Signficant Increase An increase in journey times, when compared to the Reference Case, of more than 20%.

Critically, when presenting any data in GIS format it is essential that the criteria adopted should be outlined within a key alongside the scenarios that have been compared and, if appropriate, the year of assessment.

## **Sifting Analysis**

- 65. Both the high-level reporting and any supplementary GIS analysis represent means of assessing high level outputs extracted from the model. The tendency for the high-level analysis is to be presented on an hourly basis since it provides a snapshot of the conditions across the wide area.
- 66. Having assessed the high-level outputs, it is important to prioritise those areas which require further investigation and/or the impacts are considered sufficient that network interventions may be required to minimise the impacts identified through the modelling.
- 67. As has been highlighted previously, in some areas there will be known issues or expectations for schemes to be delivered on grounds other than capacity mitigation (i.e. improve NMU provision, safety, coalescence between developments). Subject to scoping with WCC it may be necessary for these areas to be dealt with outside of microsimulation, using isolated junction assessments (Arcady, Linsig, Etc.) to ensure that there is an appropriate level of analysis for the issues that have been identified thus far.
- 68. In areas where the model is being used to determine the impacts then, a standard approach to sifting is proposed by WCC which can assist in narrowing down the amount of information, extracted from the modelling, which needs to be presented and discussed within any accompanying transport assessment work.
- 69. WCC consider that, provided the modelling has been based on a sufficient number of runs, confidence interval analysis is one such measure against which the significance of an impact can be judged<sup>1</sup>.
- 70. The following section of this note provides a suggested strategy for sifting of the model outputs which will enable the amount of information reported from the modelling to be reduced accordingly.
- 71. Sifting covers queues, journey times and link flows but it should be recognised that the link flow sifting is a lower priority assessment measure than queueing and journey times on the basis that a change in flows does not necessarily correspond to a negative impact as the impact often arises from the effect that the change in flows has on the network rather than simply the change of flows in isolation.
- 72. Each sifting strategy is described as follows:

## **Queue Sifting**

73. Whilst the initial high-level analysis is expected to consider the changes in queueing levels on an hourly basis, it is expected that any supplementary evidence will begin to assess the impacts at a more refined level. On that basis the sifting should first look to assess the impacts on an hourly basis, using the difference criteria but when the final statistical analysis is undertaken this should make use of either 5 or 10 minute intervals.

Reviewed March 2025

<sup>&</sup>lt;sup>1</sup> See 'How to reduce the gambling element in some transport planning decisions, Emily Seaman, TEC, June 2006' for a greater explanation of the use of confidence interval analysis to assess significance.

- 74. Importantly, it is considered that the analysis must be based on maximum queue lengths not averages to ensure a robust assessment.
- 75. It is expected that the analysts will undertake a series of sifting exercises whereby the impacts on the network are identified and reviewed and, if necessary, mitigation and/or network enhancements will be included within the assessment to minimise those impacts which are considered sufficiently severe to justify an intervention.
- 76. It is considered that only the final round of sifting will be presented to WCC and, at this stage, that the primary impacts will have been identified and, if necessary, mitigated such that it is considered that the evidence submitted in support of the development will be considered (by the submitting parties) to sufficiently demonstrate that any impacts associated with the proposals being tested have been mitigated and that any residual impacts are either not considered severe.
- 77. WCC offer the following sifting criteria for the assessment of queueing impacts within the model:
  - Queue impacts will only be considered IF the starting queue within the baseline is greater than 5 vehicles AND the difference between the 'with' and 'without' development scenario is also greater than 5 (i.e. Base must be at least 5 vehicles in length and development 10 vehicles in length to merit further investigation).
  - Where this criteria is achieved, for any hour within the simulation period, additional
    analysis should be undertaken in the form of confidence intervals or a similar
    statistical confidence test which establishes the statistical significance of the outputs
    obtained from the two scenarios.
- 78. This statistical analysis should then be supported via the introduction of supporting commentary on the perceived severity of the impacts (all areas where there is a statistically significant impact should be reported upon) alongside any intervention or mitigation strategy that has been derived in response to the impacts.
- 79. Any submission which makes use of supporting commentary will have to be sufficiently evidenced to demonstrate any contention offered within the analysis.
- 80. WCC will then work with all parties to establish a situation whereby the impacts are considered, and conclusions will be drawn as to whether the evidence presented thus far is considered sufficient.

#### **Journey Time Sifting**

- 81. In line with the assessment of queueing impacts, it is also expected that journey times will be reviewed in a similar manner. Critically, it is expected that the journey time analysis should consider both increases in journey times and any impacts on reliability.
- 82. As far as journey times are concerned, there are no starting conditions that WCC suggest should inform the sifting, rather the analysis should consider the sections which comprise the

- journey time route and, more specifically, any instance where the average hourly delays increase by 5% as a result of the proposals.
- 83. Once a 5% increase in delays has been identified then further analysis is considered beneficial.
- 84. At this stage delays should again be presented in a more refined interval (namely 5 or 10 minutes) and the average journey times presented for the comparative scenarios inclusive of the statistical analysis which is intended to determine the statistical significance of any changes.
- 85. If confidence interval analysis is undertaken to support the analysis of the statistical significance of any changes, then this same analysis can also be used to inform an assessment of the effects on journey time reliability at the same time as the impact analysis.
- 86. Although not specifically quantified it is recognised that the confidence interval analysis provides an indication of this measure as the upper and lower confidence bounds define the range within which the value could lie. The closer the range is to the average the more reliable the output and, conversely, a more reliable and defined the range is the greater the perceived journey time reliability.

#### **Link Flow Sifting**

- 87. As has been highlighted previously, although queueing and delays are considered to be the primary factors to be presented when impacts are being compared, analysis of the changes in link flows are also considered beneficial.
- 88. Historically, WCC have used the GEH criteria as a means of providing an indication of whether a change in flows merits further investigation. As a strategic measure, although originally intended to compare the observed and modelled flows for calibration, this is considered acceptable.
- 89. In some areas, it is also considered beneficial for the flows, and changes in flows, to also be compared to the theoretical capacity of the link to begin with. Paramics models do not allow a situation where the network has become over capacity to be realised as traffic will divert to alternative routes whenever the opportunity exists to do so.
- 90. For rural routes, the calibration of the model networks can also have a tendency to lead to links having marginally higher capacity than has been assessed on-street.
- 91. Finally, the impact on speeds in the same locations must be considered to enable a better understand of the implications of any changes in flows to be understood.
- 92. Therefore, the hourly maximum flows and speeds should both be reported and consideration should be given to the highlighting the following:
  - The absolute and percentage change in vehicles.
  - The GEH value (highlighting all instances over 5 with specific focus on 7.5 and over)
  - The % change in speeds.
  - The volume over capacity (using theoretical capacities to be agreed with WCC)

## **Summary**

- 93. The information set out within this note provides guidance on the expectations that WCC have of analysts who wish to make use of the existing suite of microsimulation models.
- 94. It is intended to be used as guidance and whilst larger site proposals will be expected to adhere to all aspects set out within this note, the requirements for assessing and reporting smaller scale developments would be commensurate with the size of the development and the expected sphere of influence.
- 95. All key areas of the wide area model must be reported upon for completeness in any case and all specific details pertaining to the reporting (both in terms of the number of measures used and overall methodology) should be agreed with WCC as part of the scoping exercise.
- 96. Scoping the reporting requirements with WCC is considered essential and that, as part of the scoping exercise, a record of which measures outlined within this note should be provided as part of the scoping.
- 97. Analysis requirements should also be scoped in full with WCC as it is recognised not all projects fit with the approach in this note. Where it is necessary to do so, WCC will also advise on any priorities in terms of focus and potential mitigation which should be considered within the impact assessment.
- 98. Once the assessment has been completed and the evidence been submitted to WCC for consideration then analysts should expect to be asked to submit all outputs to WCC and should provide evidence of the sifting process when doing so.
- 99. Outputs should be accompanied with the models and log runs which correlate to the results reported within the sifting to facilitate independent checking.
- 100. When using WCC Tier One modelling consultants, analysts can expect to receive these outputs as standard as WCC and their modelling consultants are working towards streamlining the results analysis from the modelling tools.
- 101. At a later stage, access to the Tier One consultants reporting mechanisms may be provided for a charge to cover some of the IP licencing.
